

HTA Firmware Tracker — To-Do

Things worth doing next, in roughly the order they matter.

Already done: verifying the Shure accessories via SUU, and adding headless-browser checkers for Solid State Logic, Allen & Heath, d&b, and Dante — 43 of 47 tracked items are fully automatic now.

1. Get it running somewhere that's always on

Right now it only checks automatically while the app's process is alive. Pick one:

- A spare Mac or a NAS you already have
- A cheap always-on VPS
- Ask IT if there's a house server this can live on

Once it's running continuously, everyone on the network can open the same dashboard from their own computer and see live data — no install needed on their end. Automatic daily checks also only really work once this is set up.

2. Slack integration

The plan: when a scraper detects a version change, post it to a channel instead of relying on someone opening the dashboard. The checking logic is already separate from the web routes, so this is additive, not a rewrite.

Still manual, no source found (4 items)

Nobody's fault to fix in code — these genuinely don't have a version page or API to scrape:

- **Waves:** SuperRack (installs through Waves Central, no standalone version page), WSG-HY128, Waves Plugins (release notes are per-plugin, not one overall version)
- **d&b:** DN1 Switch (no firmware entry exists for it in d&b's Download Center at all)

If any of these change (a new product page shows up, etc.), let me know and I'll take another pass.

Later, only if it becomes worth it

A real domain instead of a raw address. Once this is deployed somewhere always-on, people will reach it by typing something like `http://192.168.1.50:8000`. Fine for a small team; only worth swapping for a friendlier name (e.g. `firmware.hta.internal`) once more people are using it regularly.
